TO STUDY THE DISTRIBUTION OF RH AND KELL BLOOD GROUPS IN BLOOD DONORS

A THESIS SUBMITTED TO BABA FARID UNIVERSITY OF

HEALTH SCIENCES, FARIDKOT (PUNJAB)

IN THE PARTIAL FULFILLMENT

FOR THE AWARD OF DEGREE OF

DOCTOR OF MEDICINE

IN

IHBT

MAY, 2023

Submitted By

DR. MARYADA

DEPARTMENT OF IMMUNO HEMATOLOGY AND BLOOD TRANSFUSION
DAYANAND MEDICAL COLLEGE AND HOSPITAL
LUDHIANA, PUNJAB

DECLARATION BY THE CANDIDATE

I hereby declare that the thesis entitled **"TO STUDY THE DISTRIBUTION OF RH AND KELL BLOOD GROUPS IN BLOOD DONORS"** submitted towards partial fulfillment of the requirements for the award of **MD IN IMMUNO HEMATOLOGY AND BLOOD TRANSFUSION** degree to BFUHS is a compilation of original work carried out by me under the supervision of **Dr. Rajesh Kumar,** Professor, Department of I.H.B.T., **Dr. Amarjit Kaur**, Professor& Head, Department of I.H.B.T., & **Dr. Sonia Gupta,** Associate Professor, I.H.B.T. No part of this thesis has formed the basis for the award of any degree previously.

_____

DR. MARYADA
Department of I.H.B.T.
Dayanand Medical College & Hospital,
Ludhiana, Punjab

ACKNOWLEDGEMENT

First and Foremost, I would like to take this opportunity to acknowledge my almighty for everything. I would like to express my gratitude to my thesis guide Dr. Rajesh Kumar, Professor in department of Immune haematology and blood transfusion, Dayanand medical college and hospital Ludhiana for his continuous support, motivation, enthusiasm and immense knowledge for making me complete my research study. I thank him for offering me the chance to undertake such a wonderful, useful and interesting project in my research work.

I am highly indebted to my thesis co-guides Dr. Amarjit kaur, Head of department and Dr. Sonia Gupta, Associate Professor in department of transfusion medicine DMCH , Ludhiana for their ongoing mentorship , encouragement and never ending supply of fascinating tasks. I am grateful my Parents Dr. Anil Rooprai (Father) and Dr. Neelima Rooprai (Mother), brother Adv. Harsh Rooprai for supporting me spiritually throughout these three years of my life. I would like to thank to my colleagues Dr. Jasmeet Kaur and Dr. Kaveri Joshi for the sleepless nights together before deadlines, stimulating discussion and for all the time we had in last three years. I would like to thank Mr. Surinder singh for data collection and completing this research study. Word of thanks to Mr. Naveen Bhatia, Mrs. Namita Bansal and Mr. Gurjot singh for helping in thesis editing and completion. I would like to express my deepest sense of gratitude to my seniors Dr. Arshpreet

Kaur Batra, Dr. Manpreet kataria, Dr. Gurika Chopra for providing me valuable insights, extremely helpful guidance and total support from first day of our post graduation. The last but not the least thanks to my friends Dr. Nitish Sharma, Dr. Malvinder Singh and CA Shreyans Goyal for all time support and encouragement.

Finally, words are not sufficient to express my gratitude to my mentors, family and friends for being a pillar throughout. Without their encouragement and guidance I would have not reached this stage.

Dr. Maryada

ABSTRACT

Background: The blood transfusion aims to ensure adequate and safe blood. The Rh and Kell blood groups are highly immunogenic blood group systems. The antibodies against these antigens can result in severe hemolytic reaction. The transfusion of non phenotype blood may result in alloimmunization in patients who require multiple transfusions in hematological disorders and malignancies. The knowledge alloimunization is important for minimizing the risk of the transfusion reactions and hemolytic disease of fetus and newborn. This study will aim at providing data regarding the frequency of Rh and Kell antigen with their phenotype expression in blood donors.

Aim and Objectives: The aim is to study the frequency of Rh and Kell blood group antigens and phenotype among blood donors to compare with different groups.

Material and Methods: This will be a study of entire one year. It will include voluntary donations and the samples taken will be processed for Rh and Kell antigen typing on Neo iris Immucor automated platform that uses micro-plate haemagglutination technique and commercial antisera for phenotyping.

Results: among 5754 donors included in this study were typed for the presence of Rh (D, C, E, c, e) and Kell (K) antigens ,the most common Rh antigen in north indian population found was e(98.5%) followed by D (91.9%), C (83.8%), c (60.7%), E (19.2%). Kell (K+) antigen was present in 3.5% of donors.

Conclusions: the knowledge of antigen prevalence in a population help in providing proper antigen compatible blood for patients with multiple alloantibodies and reduce the risk of RBC antigen alloimmunization .Also, antigen profile of a particular population is useful to develop cost effective ways of providing maximum benefits of blood transfusion with least resources.

Key words: Alloimmunisation, alloantibodies, transfusion reaction, hemolytic disease of new born.

INTRODUCTION

The classification of blood based on the presence or absence of antibodies and hereditary antigenic compounds on the surface of red blood cells (RBC) is known as a blood type (also known as a blood group). Depending on the blood group system, these antigens could be proteins, carbohydrates, glycoproteins, or glycolipids. Some of these antigens can be found on the surface of numerous other cell types found in different organs. Several of these red blood cell surface antigens can stem from one allele (or an alternative version of a gene) and collectively form a blood group system[1]

Rh and Kell, are the two most significant blood group systems for determining a person's blood type (A, B, AB, and O, with + or signifying RhD status) for use in blood transfusions. Testing for blood compatibility is frequently done prior to a blood transfusion. ABO and RhD (Rh factor) typing, checking for antibodies against other blood group systems, and crossmatching, which compares the recipient's blood plasma to the donor's red blood cells as a last check for incompatibility, are all part of the comprehensive compatibility testing procedure. If an unexpected blood group antibody is detected, further testing is warranted to identify the antibody[2] and ensure that the donor blood is negative for the relevant antigen.[3]

HISTORY

The first antibody that was generated by injecting red cells from rhesus monkeys into rabbits and guinea pigs responded with the majority of human red blood cells, earning the Rh system, formerly known as the Rhesus system. One of the most immunogenic and polymorphic human blood group systems is the Rh blood group system. The molecular underpinnings of this system have been extensively studied during the last ten years and are now well understood. The Rh blood group system was described 60 years ago. In 1939, a mother gave birth to a still-born child who needed a blood transfusion. However, although the mother was given blood transfusion with ABO compatible

blood from her husband, she still experienced an adverse reaction. This has found to contain antibodies that agglutinated her husband's RBCs, even though they were compatible. Her serum agglutinated RBC's from her husband and from 80% of Caucasian ABO-compatible donors.[4] The death of the fetus and mother's adverse reaction to a blood transfusion from her husband was related. During the pregnancy, the mother had been exposed to an antigen on the fetal RBCs that was of paternal origin. Her immune system attacked this antigen which resulted in fetal death due to destruction of fetal RBC's. The mother encountered again the same paternal antigen when she received a blood transfusion from her husband. This time her immune system attacked the transfused RBCs, causing a hemolytic transfusion reaction. The antibodies responsible for this reaction led to the discovery of the Rh blood group. Therefore, the original terms (Rh factor and anti-Rh) coined by Landsteiner and Wiener, although being misnomers, have continued in common usage. The human alloantibody was dubbed anti-D, while the heteroantibody was renamed anti-LW (after Landsteiner and Wiener)[5] It was thought that the antibodies which are agglutinating produced in the mother's serum in response to her husband's RBCs were the same specificity as antibodies produced in various animal's serum in response to RBCs from the Rhesus monkey. The time it was discovered that the mother's antibodies were produced against a different antigen, the rhesus blood group terminology was being widely used. Therefore, it was abbreviated to the Rh blood group. Remarkably, only 20 years after, the effective treatment became available. Today, the Rh status of mothers-to-be is checked during pregnancy to identify those at risk of HDN. In addition, all blood transfusions are matched for the Rh status.

The Rh blood group system is one of the most polymorphic and immunogenic systems known in humans. The Rh blood group system contains 49 blood group antigens[6] among which the five antigens D, C, c, E, and e are the most important. There is no d antigen. Rh(D) status of an individual is normally described with a positive (+)

or negative (−) suffix after the ABO type (e.g., someone who is A+ has the A antigen and Rh(D) antigen, whereas someone who is A− has the A antigen but lacks the Rh(D) antigen). In the past decade, intense investigation has yielded considerable knowledge of the molecular background of this system. The genes encoding 2 distinct Rh proteins that carry C or c together with either E or e antigens, and the D antigen, have been cloned, and the molecular bases of many of the antigens and of the phenotypes have been determined. The Rh glycoprotein, a similar protein, is necessary for the Rh protein complex to assemble in the erythrocyte membrane and for the production of Rh antigens.

Clinically speaking, Anti-D results in the most severe form of HDN and used to be a significant factor in foetal demise. Since the development of anti-D immunoglobulin and meticulous monitoring of pregnancies at risk, the prevalence of HDN caused by Rh D incompatibility has significantly decreased. All cases, however, cannot be avoided, and RhD alloimmunization continues to be a significant contributor to disease.[7] Clinical problems are caused by RBC destruction as a result of an alloantibody's interaction with RBCs containing the relevant antigen. Maternal IgG antibodies that cross the placenta attach to foetal RBCs that are antigen-positive and begin to degrade them, resulting in anaemia and HDN. Prior to the introduction of prophylactic Rh immunoglobulin, anti-D commonly resulted in foetal brain damage (kernicterus) and even death because of elevated levels of bilirubin (erythroblastosis fetalis). A significant number of pregnant women still develop alloimmunization despite the widespread use of prophylactic Rh immunoglobulin for a variety of reasons, such as non-administration of Rh immunoglobulin, unrecognised miscarriage, leakage of foetal RBCs into the maternal circulation late in pregnancy, and exposure to maternal D-positive RBCs while in utero (grandmother effect)[8] The blood type of a foetus can be predicted by analysis of DNA generated from the foetus using modern molecular techniques. It's interesting to note that a foetus with maternal anti-A/B is less likely to develop HDN

due to anti-D. This is probably because the naturally occurring anti-A/B removes ABO-incompatible RBCs quickly. Additionally, foetuses with R2 RBCs have more severe anaemia than those with R1 RBCs because the number of copies of the D antigen per RBC is larger in the R2 haplotype (range: 14 000 to 16 000) than in the R1 haplotype (range: 9000 to 14 600). Additionally, there is evidence to suggest that male foetuses have more severe HDN than female foetuses[9] The presence of maternal anti-Rh IgG must be determined in order to diagnose HDN. These antibodies are difficult to distinguish since they do not lyse cells or even cause agglutination in vitro, yet in vivo they kill Rh D-positive foetal RBCs. So, the Coombs test is employed. Antibodies that bind to anti-D antibodies are used in this test. Robin Coombs, who pioneered the use of antibodies that are directed against other antibodies, is honoured by having his name associated with the test. The direct Coombs test, which diagnoses HDN, looks for maternal anti-D antibodies that have already attached themselves to foetal RBCs. Indirect Coombs test: This test detects anti-D antibodies in the mother's serum and is used to prevent HDN.

KELL BLOOD GROUP:

HISTORY

Studies of the Kell antigens have given insight into the emergence of polymorphic features in the context of human evolution since the Kell blood group system was identified in 1946. The Kell blood group system is characterised by a high degree of polymorphism (genetic variation). The Kell system is the third most frequent blood group to result in transfusion reactions and erythroblastosis fetalis due to antibodies produced against its antigens, following the Rh and ABO systems. The disease was named after Mrs. Kelleher, a woman whose newborn child suffered hemolytic disease as a result of anti-Kell antibodies (the baby's RBCs expressed K antigen, which was bound by anti-K in the mother's serum).Since then, 25 Kell antigens have been identified; they are expressed at various frequencies in various

populations. However, the original K antigen continues to be crucial for HDN and transfusion therapy.

The Kell antigen system, often referred to as the Kell-Cellano system, is a system of antigens on the surface of human red blood cells that play a significant role in blood type determination and are targets for autoimmune or alloimmune illnesses that cause the destruction of red blood cells. K, k, Kpa, Kpb, Jsa, and Jsb are the Kell antigens.[10]After those in the ABO and Rh systems, anti-K is the immunological red cell antibody that is most frequently found. The most common kind of anti-K is an IgG class alloantibody. When transfused with blood carrying a particular Kell antigen, a person lacking that antigen may generate antibodies against Kell antigens. This is especially true for the "K" antigen, which has a somewhat low frequency (9%) and a relatively high antigenicity among Caucasian people. Anti-K is a major worry for newborn hemolytic illness since it can also happen after transplacental haemorrhage (TPH) related to childbirth. Subsequent blood transfusions may be characterised by hemolysis, or the antibodies' killing of the new cells, after the development of anti-K. Hemolysis is extravascular because anti-K does not bind complement. In order to prevent hemolysis, blood from donors who are also K0 must be transfused into people who lack K antigens (K0) but have developed an antibody to a K antigen. When the body creates an antibody against a blood group antigen on its own red blood cells, autoimmunity hemolytic anaemia (AIHA) takes place. The antibodies cause the red blood cells to be destroyed, which results in anaemia. Similar to this, a pregnant woman could produce antibodies that attack foetal red blood cells, leading to damage, anaemia, and hydrops fetalis in a condition known as HDN. When anti-Kell antibodies are involved, both AIHA and HDN may be severely affected.[11] Because, after those of the ABO and Rhesus blood type systems, they are the most immunogenic antigens. K is ranked second only to D in terms of immunogenicity, excluding ABO. Pregnancy and blood transfusions appear to be the primary causes of anti-K.[12]

After the antigens of the ABO and Rh blood group systems, the K antigen is the most immunogenic antigen in clinical settings. Anti-Kell antibodies typically belong to the IgG antibody class (IgM is far less common). Anti-K, anti-K, anti-Kpa, and anti-Jsb antibodies have all been linked to transfusion responses, which can occasionally be very serious.[13] Patients with Ko have experienced a deadly hemolytic transfusion reaction as a result of the development of anti-Ku. Anti-Kell is a significant factor in HDN. Moms who have previously received numerous blood transfusions are more likely to develop it, but mothers who have developed a sensitivity to the Kell antigen during prior pregnancies are also at risk. HDN attributed to Kell sensitization, in contrast to Rh and ABO sensitization, is brought on by anti-K inhibiting foetal RBC production. In contrast to Rh and ABO, Kell antigens are expressed on the surface of RBC progenitors, and in the foetal liver, anti-K enhances macrophages' immunological killing of K+ erythroid early progenitor cells (rather than only mature foetal RBCs). Since haemoglobin is absent from the RBC precursors, less bilirubin is generated during hemolysis, which reduces the likelihood of jaundice in the newborn period, But the underlying anaemia can be really bad.[14]

AIM AND OBJECTIVES

To study the frequency of Rh and Kell blood group antigens and phenotypes among blood donors and to compare them with different groups.

REVIEW OF LITERATURE

The Rhesus blood group system is one of the most polymorphic and highly immunogenic systems in humans. Because of its high and strong immunogenicity Rh D antigen testing is mandatory before issuing a compatible blood. Both of them may cause severe hemolytic transfusion reaction and hemolytic disease of fetus and new born. Exposure of Rhesus negative individuals to Rhesus positive blood through transfusion or pregnancy is most likely to stimulate production of Rhesus antibodies. These antibodies may cause Hemolytic Disease of Fetus and Newborn and Delayed Hemolytic Transfusion Reaction (DHTR). Like Rhesus antibodies, Kell antibodies may also cause HDFN and DHTR. There are five major antigens i.e. DCEce in the Rh blood group system. On the other hand from the immunogenicity point of view Kell antigen is next to the Rh system. The common antigens of the Rhesus and Kell blood group systems are also frequently tested in blood donors and patients because of their clinical relevance. Antigens belonging to the Rh and Kell blood group systems are of major clinical significance because of their immunogenicity and the potential of their consequent antibodies to cause in vivo destruction of exogenous RBCs. Despite the widespread use of transfusion, there are sparse data on the prevalence of Rh and Kell system antigens and their ethnic variability. The objective of this study was to determine the prevalence of the five major Rh and Kell (K) system antigens among blood donors of groups in a tertiary care hospital with the goal of understanding alloimmunization risk in transfusion recipients and improving transfusion safety through the availability of resources, such as antisera for extended RBC typing and antigen panels for alloantibody detection. The clinical importance of any blood group antigen is determined by its ability to induce antibody formation and the ability of these antibodies to cause in vivo destruction of red blood cells. Of the blood group antigens, the Rh and Kell antigens are particularly clinically significant because of their immunogenicity, high risk of

alloantibody formation.[15] and ability to cause severe hemolytic transfusion reactions.[16]

Nomenclature Number of Rh antigens: 49, ISBT symbol: Rh, ISBT number: 004, Gene symbols: RHD and RHCE, Gene names: Rhesus blood group, D antigen; and, Rhesus blood group, CcEe antigens. There are more than 52 antigens in the Rh blood group discovered at present, but the major ones are D,C,E, c and e. In the Kell blood group system, more than 24 antigens have been discovered, among them Kell (K) and k (Cellano) is the most important. The phenotype of a blood group of an individual is the observable expression of the genes inherited by the person and reflects the biologic activity of the genes. The presence or absence of antigens on red cells as determined by serological testing represents the phenotype[17] The phenotype of clinically significant blood group antigens on the donor RBC is required to be known at times when alloimmunization is particularly undesirable, as in young females, pregnant women, and patients who are expected to require repeated transfusions in life, such as thalassemia or sickle cell disease patients. When selecting blood for transfusion to such patients, it would be useful if we have access to already phenotyped RBCs of donor population so that particular antigen typed blood can be given to such patients to prevent alloimmunization.[18] The typing of blood group antigens and determination of phenotype for blood and blood components are a prerequisite for an efficient and safe blood transfusion. Rh antibodies are usually immunoglobulin G, and they are produced early during life (4-6 months). The knowledge of the distribution of Rhesus antigen in a population is critical in managing a transfusion service in areas such as antenatal serology, paternity testing as well as selecting compatible blood and blood products. Even after karl Landsteiner’s discovery in 1990, transfusion reactions were still prevalent.[19]

MOLECULAR GENETICS OF RH BLOOD GROUP:

The Rh locus is located on the long arm of chromosome 1 (on 1p36-p34). It contains the RHD and RHCE genes, which lie in tandem. The RHD and RHCE genes are structural homologs and result from a duplication of a common gene ancestor. RHD and RHCE each contain 10 exons and span a ~75-kb DNA sequence. The RHD gene is flanked by two 9-kb, highly homologous sequences called "Rhesus boxes". It is thought that unequal homologous recombination confined to the Rhesus boxes is a common cause of the deletion of the RHD gene, which is found in up to 40% of the population. The RHD and RHCE genes each encode a transmembrane protein over 400 residues in length that traverses the RBC membrane 12 times. The RhD protein only differs from the common form of the RhCE protein by about 35 amino acids. The RhD protein bears the D antigen which has over 30 epitopes. The RhCE protein carries the epitope for the C or c antigen on the second extracellular loop, and the epitope for the E or e antigen on the fourth extracellular loop. A number of nucleotide substitutions in the RHCE gene in turn cause a number of amino acid changes in the RhCE protein, but two polymorphisms are thought to be key in producing the polymorphic antigens on this protein, i.e., the S103P polymorphism (produces the C or c antigen, respectively), and the P226A polymorphism (produces the E or e antigen, respectively).

RH ANTIGENS

D antigen

The D antigen is a collection of conformation-dependent epitopes along the entire RhD protein. While in most D-negative Caucasians there is a deletion of *RHD*, in other populations (notably Japanese and African blacks) the D-negative phenotype is associated with a grossly normal *RHD,* and the reason for the lack of expression of the D antigen is not known.

CcEe antigens

The RhC/c and RhE/e polymorphisms are caused by nucleotide substitutions in *RHCE.*[20-21] While 6 nucleotide substitutions causing 4 amino acid changes are associated with the C to c polymorphism, only the Ser103Pro polymorphism strictly correlates with C/c antigenicity. However, Pro102 appears to be a critical part of the c antigen[22-23] The presence of 2 adjacent proline residues (102 and 103) would be expected to form a relatively rigid structure that is resistant to changes in nearby amino acid residues and may explain the relatively low number of c variants as compared with other Rh antigens. However, variants of the e antigen have been described[24] showing that the requirements for expression of the e antigen are not fully understood.

Common Rh phenotypes

The most common Rh haplotype in Caucasians, Asians, and Native Americans is DCe. In Blacks, the Dce haplotype is slightly more common[25] In Caucasians, the Rh D-negative phenotype results from a deletion of the RHD gene. About 15% of Caucasians are Rh D-negative.In Africans, there are three molecular backgrounds that give rise to the Rh D-phenotype which is found in 8% of the population. One is the RHD gene deletion that is common in Caucasians. The other two mechanisms are inheriting a RHD pseudogene (contains a duplication of nucleotides that introduces a premature stop codon) or inheriting a RHD hybrid gene (contains nucleotide sequences from the RHCE gene, produces no D antigen and abnormal C antigen)[26]

Uncommon Rh phenotypes

The D antigen contains over 30 epitopes. Variations of the D phenotype arise when these epitopes are only weakly expressed ("weak D phenotype") or when some are missing ("partial D phenotype"). Weak D: all D antigen epitopes are present but are underexpressed . "Weak D" is a Rh phenotype found in less than 1% of

Caucasians and is only slightly more common in African Americans[27] It is typically caused by a single amino acid switch in the transmembrane region of the RhD protein. This disrupts how the RhD protein is inserted into the RBC membrane, reducing the level of expression of RhD. In most cases, adequate levels of D antigen are present and because there has been no change in D epitopes, the formation of anti-D is prevented. Therefore, individuals with the weak D phenotype can receive Rh D-positive blood.

Partial D: some D antigen epitopes are missing. In contrast, people who have been identified as having the "partial D" phenotype should not receive Rh D-positive blood but in practice, people with partial D are difficult to identify. This phenotype is usually caused by the creation of a hybrid RhD and RhCE protein. The hybrid protein is similar enough to RhD to be correctly inserted in the RBC membrane, but it lacks several epitopes found on the complete RhD protein. If a person with the partial D phenotype encounters the complete D antigen on transfused RBCs, they may form anti-D and suffer from a transfusion reaction.

The D antigen is highly immunogenic and induces an immune response in 80% of D-negative persons when transfused with 200 mL of D-positive blood[28] For this reason, in most countries D typing is performed routinely on every blood donor and transfusion recipient so that D-negative patients receive D-negative RBC products. Consequently, clinical complications due to mismatched transfusions are infrequent. In contrast, despite the use of immunosuppressive therapy with anti-D immunoglobulin prophylaxis, D alloimmunization in pregnancy still occurs. Anti-D, anti-C, anti-E, and anti-e have all been involved in hemolytic transfusion reactions, particularly delayed reactions[12] Routine blood typing for Rh D status in both blood donors and transfusion recipients has reduced the incidence of transfusion reactions caused by anti-D. But sensitization to other Rh antigens can be a problem in transfusion medicine, particularly in patients with sickle cell anemia (SCA). SCA is more common in Blacks, and the treatment

of SCA involves blood transfusions. Blacks are also more likely to express variants of the Rh e antigen, and therefore produce anti-e, along with other Rh alloantibodies, which increases the difficulty in finding Rh-compatible blood donors. The D antigen accounts for about 50% of cases of maternal alloimmunization; the remainder is due mainly to incompatibility to K, c, C/G, E, and Fy^a antigens and to low incidence antigens in Rh.[29-30]

The Kell blood group system is complex and contains many antigens that are highly immunogenic. These antigens are the third most potent, after those of the ABO and Rh blood groups, at triggering an immune reaction. Antibodies that target Kell antigens causes transfusion reactions and HDN. In the case of HDN, ABO and Rh incompatibility are more common causes. However, disease caused by maternal anti-ABO tends to be mild, and disease caused by maternal anti-Rh can largely be prevented. The infrequent cases of HDN caused by Kell immunization tend to result in severe fetal anemia because maternal anti-Kell target fetal RBC precursors, suppressing the fetal production of RBCs. The Kell blood group system consists of 36 high-prevalence and low-prevalence antigens; it was the first blood group system discovered after the introduction of antiglobulin testing. Anti-K was identified in 1946 in the serum of Mrs. Kelleher. Nomenclature Number of Kell antigens: 25 ,ISBT symbol: KEL,ISBT number: 006, Gene symbol: KEL, Gene name: Kell blood group**.** In this blood system, 27 antigens are present although only Kell (K1) and cellano (K2) are clinically important. After ABO and Rh antigens, they may be immunogenic since they have been linked to severe HDN.[31] Kell antigens are grouped in antipodal set pairings with some antigens that have yet to find antithetical partners. KEL1 (K, "Kell") and KEL2 (k, "Cellano"); KEL3 (Kpa), KEL4 (Kpb), and KEL21 (Kpc); KEL6 (Jsa) and KEL7 (Jsb) are antithetical antigens[32] KEL4 in contrast to other common antigens is linked to two antithetical antigens KEL3 and KEL21. Individuals with negative KEL2, KEL4, or KEL7 antigens have

uncommon phenotypes, Ko (null) phenotype is present in individuals in which all Kell antigens are absent. The expression of Kell antigens is determined by different alleles of the *KEL* gene which is organized into 19 exons. Single nucleotide polymorphisms are the most common cause of different Kell phenotypes. Kell antigens are expressed on the type II Kell glycoprotein which spans the red blood cell (RBC) membrane once and is linked through a single disulfide bond to the XK protein, an integral membrane polypeptide that expresses the Kx blood group antigen (XK1). The absence of XK protein leads to the Mc Leod syndrome that is characterized by neuromuscular abnormalities, mild hemolysis, and RBCs acanthocytosis with a greatly reduced amount of the Kell protein and all of its antigens (Mc Leod phenotype)[33-34] Nucleotide changes that occur in the *KEL* gene may give raise to silent alleles (K_0 alleles) responsible for the lack of Kell antigen expression, the so-called Kell null phenotype (K_0 phenotype). In addition, several nucleotide changes affecting the *KEL* gene lead to depressed or weak Kell antigens, which is termed K_{mod} phenotype[35-37]Antibodies that target Kell antigens are commonly IgG that are anti-K1, anti-K2, anti-K3, and anti-K7 that become the cause of hemolytic disease in newborns and transfusion reaction**.** The K1 antibody (antiK1) is responsible for severe anemia in 10% of cases[34] The Anti-K, anti-Kp a , anti-k, and Anti-Js 1 antibodies are responsible for producing a more lethal transfusion reaction. Anti-Kell is the most common immune red cell antibody outside ABO and Rh systems and is considered clinically significant, both from point of view of causing severe hemolytic disease of the fetus and newborn and hemolytic transfusion reaction. Of the common Rh and Kell antigens, D is highly immunogenic followed by “K,” “c,” and “E.”

MOLECULAR GENETICS

The gene KEL, located on chromosome 7 at position 7q33, is organized into 19 exons of coding sequence.4 The KEL gene is highly polymorphic, with different alleles at this locus encoding the 25 antigens that define the Kell blood group. Single base mutations

encoding amino acid substitutions are responsible for the different Kell antigens. Several different mutations (e.g., point, frameshift, or splice site mutations) have been found that result in the rare null phenotype Ko[25,38] The Kell antigens are located on a glycoprotein that consists of 731 amino acids and spans the RBC membrane once. The N-terminal domain is intracellular, and the large external C-terminal domain is highly folded by disulfide linkages. The Kell glycoprotein is a member of the neprilysin (M13) family of zinc endopeptidases associated with the cleavage of big endothelins, but how this relates to the physiological role of the Kell glycoprotein remains unclear. Kell antigens were once thought to be restricted to blood cells of erythroid origin (i.e., RBCs and their precursors), but they have recently been found to be expressed in myeloid tissues[39] The Kell antigen is also expressed in a small amount on a number of organs including lymphoid organs, muscle (both cardiac and skeletal), and the nervous system[25]The Kell glycoprotein is an endothelin-3-converting enzyme. By cleaving an inactive precursor (big endothelin-3), it creates active endothelin-3, which is a potent constrictor of blood vessels. The Kell antigens are peptides found within the Kell protein, a 93-kilodalton transmembrane zinc-dependent endopeptidase which is responsible for cleaving endothelin-3[40] The Kell protein is anchored to the surface of the RBC by being linked to an integral RBC membrane protein, XK, by a single disulfide bond. XK is a transmembrane protein that traverses the RBC membrane 10 times. If XK is absent, the multisystemic syndrome, McLeod's syndrome, results. The Kell protein has both sequence and structural homology to a large family of zinc-dependant endopeptidases (enzymes that cleave proteins within the peptide chain, not near the N or C terminus). The Kell protein and other proteins in this family contain a pentameric sequence which is essential for zinc binding and catalytic activity.

Common Kell phenotypes

The Kell blood group system is complex. The Kell locus is highly polymorphic and gives rise to many Kell antigens. There are, however, two major codominant allelic genes that produce two important antigens: K and k (previously known as Kell and Cellano, respectively), which differ by a single amino acid. The k antigen is more common than the K antigen in most populations, the K-k+ phenotype is found in 98% of Blacks and 91% of Caucasians.

Uncommon Kell phenotypes

Null phenotype

The Kell system has a rare null phenotype, K_o, in which RBCs lack all Kell antigens. Individuals with this phenotype are healthy but produce anti-Ku when they encounter RBCs that do express Kell antigens. Anti-Ku is capable of causing a mild to severe transfusion reaction with at least one fatal case being reported[13] Therefore, if K_o individuals ever require a blood transfusion, they should only be transfused with K_o blood products.

McLeod syndrome

In the RBC membrane, the Kell glycoprotein is covalently linked to the XK protein, a multipass membrane protein thought to have a role in transport. In the absence of XK, a condition called McLeod syndrome, Kell antigens are only weakly expressed and the RBCs are abnormal with spiky projections (acanthocytosis). Systemic findings include muscular dystrophy, cardiomyopathy, psychiatric disturbances, and neurological defects, such as loss of reflexes and movement disorders.[41]

In McLeod Phenotype, Kell protein is chemically bonded to the XK protein which is hypothesized to perform the function of transportation, in the membrane of red blood cells.[42] When XK is missing, a disease known as McLeod syndrome develops, in which Kell antigens give very

light expression and erythrocytes have abnormal spiny extensions (acanthocytosis). Muscular dystrophy, heart problem, mental abnormalities, and nervous system impairments such as malfunction of reflexes and balance abnormality are among the main results[41]Antibodies formed as a result of Kell antigen can trigger transfusion reactions and neonatal HDN. It usually affects women who have had multiple blood transfusions, but it can also affect moms who had sensitization to Kell antigen in early gestation. Kell sensitization, unlike Rh and ABO hypersensitivity, is produced by anti-K antibodies limiting RBC synthesis in the fetus. Kell antigens are present in the peripheral area of RBC precursors by the tenth week of life, and Kell antibodies promote the macrophages that cause immune destruction of progenitor cells in the liver of the fetus. Since RBC precursors are devoid of Hb, a small quantity of bilirubin is mixed in amniotic fluid during the hemolysis, and anti-Kell antibodies cause fetal anemia by destroying fetal erythroid progenitors[43-44] Erythropoiesis is the development of mature red blood cells from erythroid progenitor cells. During early erythropoiesis, the expression of Kell glycoprotein is high implying a key function in the early phases of erythropoiesis. At the progenitor level, Maternal Kell antibodies decrease erythropoiesis in fetuses which lowers the number of reticulocytes associated with severe anemia as well as reduced bilirubin.[45] Kell alloimmunization may cause severe anemia and hydrops in newborn babies, due to early cell death before red blood cells collect sufficient hemoglobin levels.[44]

Fortunately, the prevalence of K antigen is low (9% in whites), and the chance of receiving a K+ unit is small. The K antigen is more potent at triggering an immune reaction than the k antigen. Its higher level of antigenicity may be because, unlike other Kell antigens, it is *not* glycosylated at residue. Observation by Levine *et al*. that the development of stillborn fetus was associated with immune reaction to paternal antigens led insights into the complexities of Rh blood group system.[46]

Various studies are conducted in India to find out prevalence of Rh and Kell blood group among whole blood donors.

A study of New Delhi, where Samples from randomly selected blood donors (both voluntary and replacement) coming for blood donation were collected for extended antigen typing during January 2009 to January 2010, a total of 3073 donors were typed during the study period. The most common Rh antigen observed in the study population was e (98%) followed by D (93.6%), C (87%), c (58%) and E (20%). The frequency of the Kell antigen (K) was 3.5 per cent, while that of Cellano (k) was 99.97 per cent. (2009).[47]

In Cote d'Ivoire study, samples of 605 blood donors for phenotypic profile of Rh and Kell, were found to be representing 92.93% of the blood donors to be RhD Positive while 46 blood donors representing 7.07 were found to be RhD negative. In the Kell blood group system, 5 blood donors (0.77%) were typed as K antigen positive and 645 (98.08%) as k antigen positive antigens. Accordingly, the K−k+ phenotype was the most common in these donors (98.92%).(2014)[48]

Another study of Phenotype frequencies of Rh and Kell blood groups, shows the result of clear predominance of Rh1 (D) positive (89.81%) compared to Rh-1 (d) negative (10.19%). CcDec was the most common phenotype (38.95%), followed by ccDee, ccdee and CcDEe. For the Kell system, the predominance of Kell-1 subjects was clearly observed at frequency of 93%. The Rh D allele was the most prevalent (68.08) among Rh blood type alleles while the Kell-1 (96.44%) was frequent among the alleles of Kell blood group system.(2016)[49]

Prevalence of Rh and Kell antigens in a population varies with race, ethnicity, and geographical location. Phenotypic distribution and allelic frequencies of blood group antigens are one of the major determinants of alloimmunization risks. Phenotypic profiling and assessment of allele frequencies help in evaluating the distribution of antigens in a particular

population and at the same time helps in estimating the chances of getting compatible blood units for patients who have developed multiple antibodies[50]Rh blood group is one of the most complex and polymorphic blood group systems. Observation by Levine *et al*. that the development of stillborn fetus (HDN) was associated with immune reaction to paternal antigens led insights into the complexities of Rh blood group system[46]

In a latest study in 2019 of distribution of RH and Kell blood group antigens among blood donors in a tertiary care hospital, on phenotyping for Rh and Kell antigens 'e' antigen have the ubiquitous distribution and was found to have the highest frequency 486 (97.2%) followed by 'D' antigen 472 (94.4%), 'C' antigen 426 (85.2%), 'c' antigen 320 (64.0%) and 'E' antigen 103 (20.6%). Overall frequency of Kell (K) antigen was only 2.6%[51]

Assessment of rhesus and kell blood group antigens, phenotypes, and their allelic frequencies in North Indian blood donors, in *Lady Hardinge Medical College, Connaught Place, New Delhi, India.* The most common antigen in North India donor population was "e" (95.6%) followed by "C" (89.6%), "c" (57.7) and "E" (17.29%) in that order. In the group of "D" positive donors, the frequency of "e" antigen was 95.4%, whereas it was present in 100% of Rh (D) negative donors. "C" was present in only 5% Rh (D) negative donors, but was present in 93.35% of Rh (D) positive donors. Prevalence of "c" and "E" was found to be more variable, "c" was found in 56.04% of Rh (D) positive donors and in 98% of Rh (D) negative donors. "E" was identified as least prevalent antigen (among C, c, E, e) with percent positivity in Rh (D) positive and Rh (D) negative donors being 17.95% and 1.92%, respectively. Concomitant presence of "C" with "D" was noted in 93.35% of donors.[52]

To determine the phenotype prevalence of the Rh and Kell blood group systems in the blood donors in Bangladesh, a descriptive cross sectional study was done in the laboratory of Department of Transfusion Medicine, Bangabandhu Sheikh Mujib Medical University, during the period of 1st January 2020 to 31 December 2020. A study on Prevalence of Rhesus & Kell phenotypes among blood donors of Bangladesh, pubcomprised of 256 whole blood donors. The Most probable Rhesus Genotype CDe/CDe (R1R1) is highest (48.4%) and CDe/CDE (R1Rz) & cDE/cDE (R2R2) both are lowest (0.4%). Kell Genotype kk is highest (99.2%) and Kk is lowest (0.8%).[53]

A study article in journal of blood disorders and transfusion on, Phenotype Prevalence of Blood Group Systems (ABO, Rh, Kell) in Voluntary, Healthy Donors-Experience of a Tertiary Care Hospital in Delhi, North India. This Study included a total of 2769 voluntary blood donors in which Rh antigen was found positive in 93.8% and negative in 6.2% donors. Amongst Rh positive antigens, e was the most common (98.7%) followed by C (91.8%), c (55.2%) and E(21.1%). DCe/DCe (44.7%) was the most common phenotype. Distributions of Rh minor antigens were also assessed in different blood group and were found similar. For the Kell System, only 1.6% was K positive which is less than previous study from India.[54]

Study on ABO, Rh, and kell blood group antigen frequencies in blood donors at the tertiary care hospital of Northwestern India, SMS hospital, Jaipur Was held in December 2020, published in asian journal of transfusion science. A total of 8067 donors were included in this study. The most common Rh antigen found was e(99.3%) followed by D (93.8%), C (85.4%), c (60.1%), E (17.5%). R1r (DCCee) was the most common phenotype in our study (39.5%). Kell (K+) antigen was present in 2.7% of donors whereas 97.3% of the donor population is Kell negative. They have determined the prevalence of Rh antigens and Rh phenotypes in blood donor and derived the allele frequencies in

the same population.[55] The most common Rh phenotype observed was DCCee followed by DCcee > DCcEe > ccee > DccEe > Dccee > DccEE > Ccee > DCCEe.

Primary goal of transfusion is to provide safe blood to the patient. The concept of safe blood started with the discovery of the ABO blood group in 1901and Rh blood group in 1939–1940[56]Other blood group systems such as Kell, Kidd were discovered later. Hence, The Knowledge of prevalence of different blood group antigens in any population is very important for department of Immune Hematology and Blood Transfusion and Transfusion services policies. The distribution of Rh and Kell antigen varies from race to race and among different ethnic groups. It is always helpful in managing the cases of multiple transfusions like thalassemia, sickle cell anemia, cancer patients and patients on dialysis etc., who are prone to develop antibodies against blood group antigens. Antigens of the major blood group systems play a very important role in determining the outcomes of transfusion in recipients of blood and blood components.

MATERIAL AND METHODS

Study period: 1 year (1/03/2021- 28/2/2022).

Study population: whole blood donors in the department of immune haematology and blood transfusion DMCH.

Inclusion Criteria

- The whole blood collected in Integral bags.

Exclusion Criteria

- The whole blood collected in Single bags, Double bags, and Triple bags.
- Donors testing positive for HBsAg, HCV, and HIV antibodies, syphilis and malaria.

Informed consent: informed consent was obtained from all whole blood donors at the time of donor screening as per standard operating procedure.

METHOD OF COLLECTION OF DATA

After sterilizing and drying the phlebotomy site with 70% isopropyl alcohol, blood collection procedure was performedfrom the ante-cubital vein following all aseptic measures, as per the transfusion medicine technical manual guidelines, the tube containing EDTA as an anticoagulant will be selected for antigen typing. All blood samples were phenotyped and processed for ABO, Rh (C, c, E, e, and D), and Kell (K) antigens on a fully automated system (Galileo, Immucor) Neo Iris Immucor automated platform that uses microplate heamoagglutination technique for typing with IgM monoclonal commercial antiserum for Rh and Kell (K) phenotyping. Rh phenotyping was be done by using monospecific antisera: Anti-D, anti-E, anti-C, anti-c, anti-e and kell phenotyping was performed by using anti-K.

Any NTD (no type determined) results determined by the instrument well be further tested and confirmed using the test tube method.

OBSERVATION AND RESULTS

During the study period of one year total number of donor were 27484. Out of these donors Rh and Kell Blood grouping was done on 5754 samples. These blood samples fulfilling the inclusion criteria were included in the study. They were analysed for different demographic parameter and study was performed on all of them. The results were as follow:

DIFFERENT AGE GROUPS

Among 5754 donors, 44.9 % (2586) of the donors had age in between 18 to 30 years, while 26.3% (1516) of donors were of age 31-40 years. 23.6% (1356) of donor population was seen between 41-50 years and 5.1% (296) population of age 51-60 years

Table- 1 Distribution of donors of different ages

AGE GROUP	No. of Donors	Percentage
18-30	2586	44.9%
31-40	1516	26.3%
41-50	1356	23.6%
51-60	296	5.1%
Total	5754	100.0%

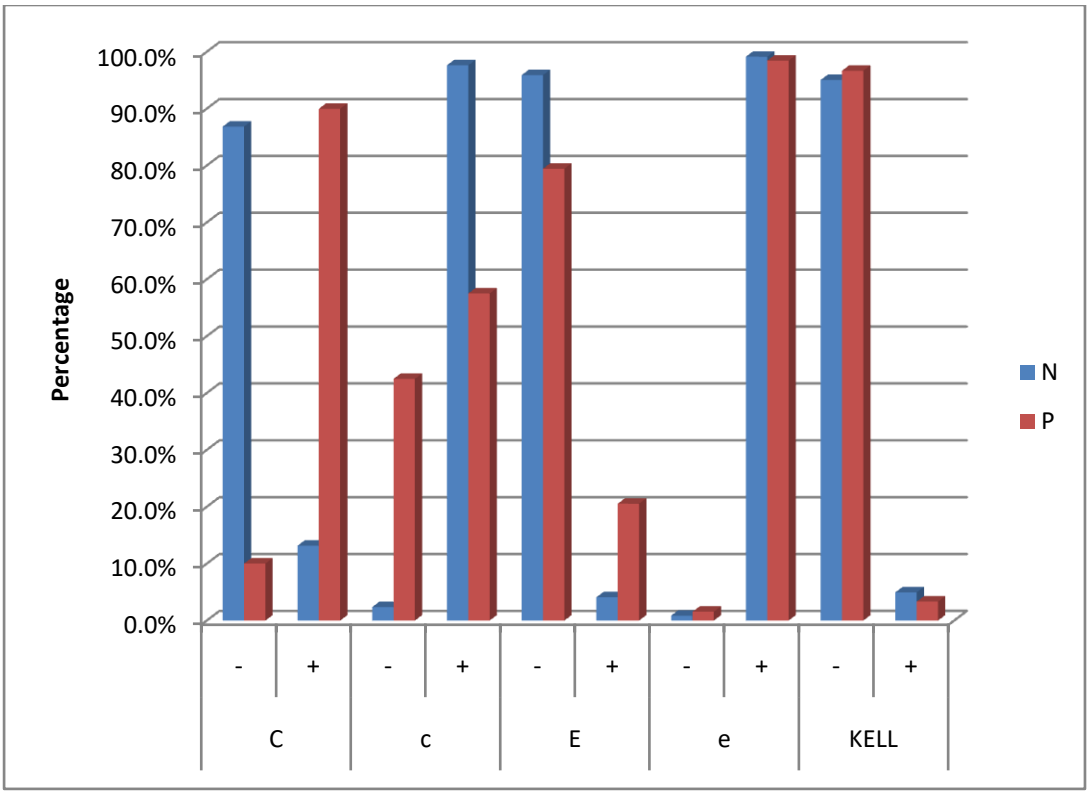

Figure 8. Distribution of Antigens in Rh positive and negative donors:

DISTRIBUTION OF C, c, E and e ANTIGEN

Out of 5754 donors, 83.8% (4821) were “C” antigen positive and 16.2% (933) were negative for C antigen.

Table- 9 Distribution of C antigen in donors:

C ANTIGEN	No. of donors	Percentage
Negative	933	16.2%
Positive	4821	83.8%
Total	5754	100.0%

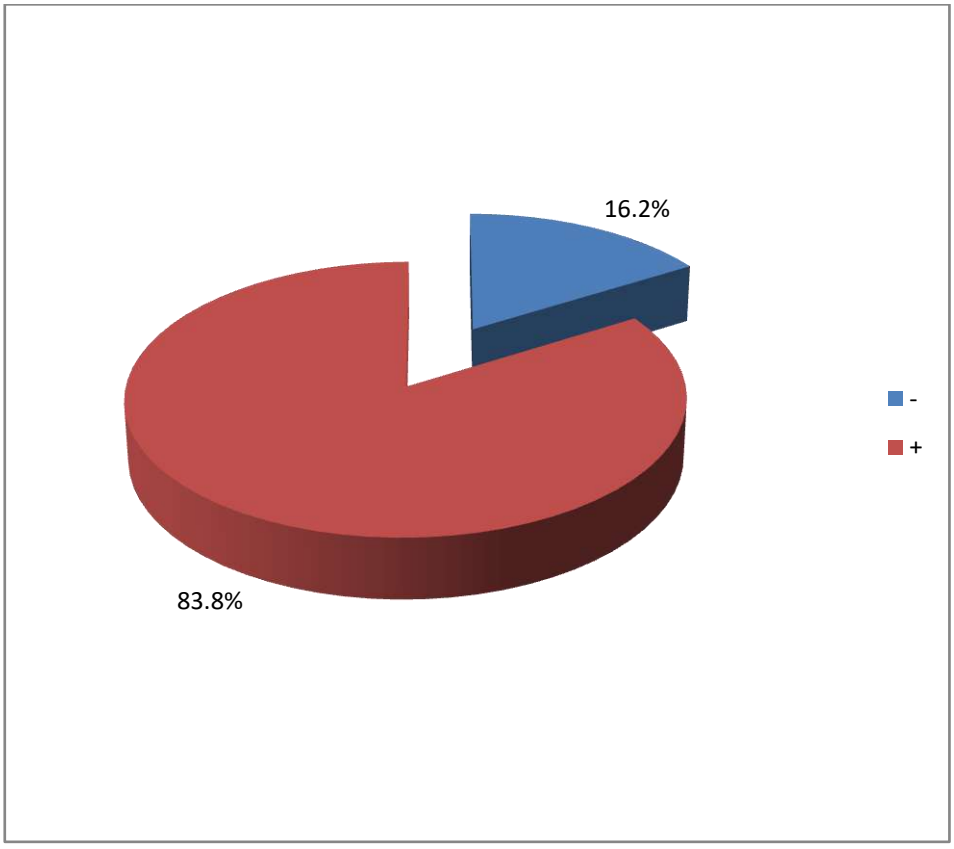

Figure 9 Distribution of C antigen in donors:

Distribution of c antigen in donors:

Among 5754 blood donors, 60.7% (3495) were found to be positive for “c” antigen and 39.3% (2259) were negative.

Table- 10 Distribution of c antigen in donors:

c ANTIGEN	No. of donors	Percentage
Negative	2259	39.3%
Positive	3495	60.7%
Total	5754	100.0%

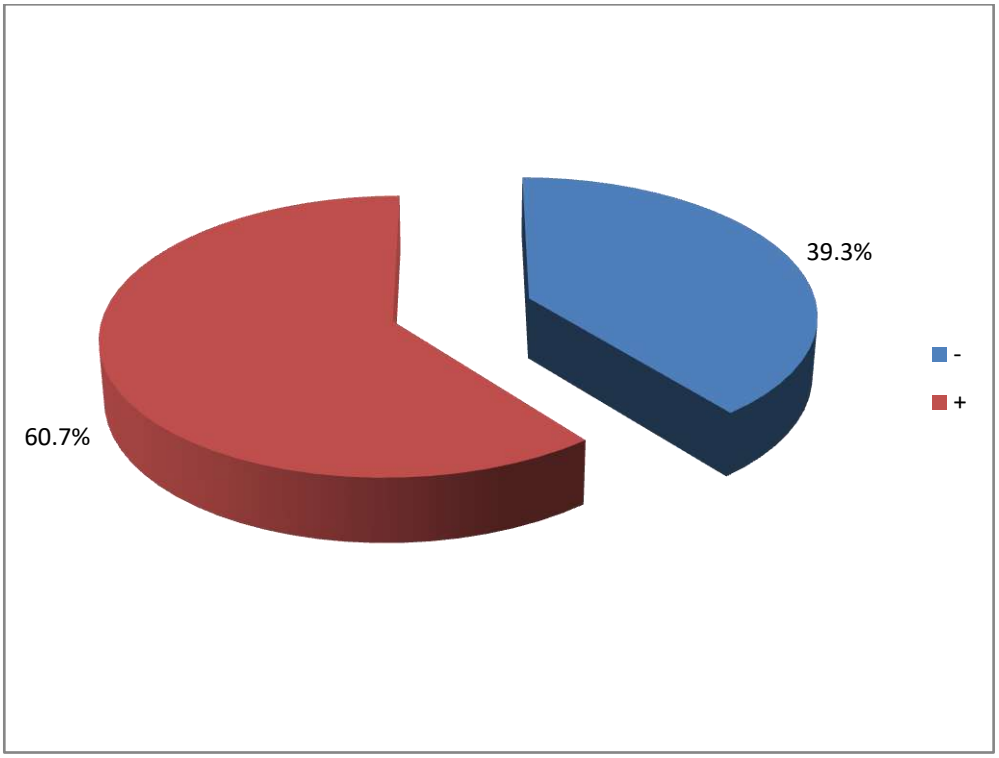

Figure 10 Distribution of c antigen in donors:

Distribution of E antigen in donors

In 5754 blood donors, 19.2% (1106) donors were seen “E” antigen positive and 80.8% (4648) of them were found to be negative.

Table- 11 Distribution of E antigen in donors:

E ANTIGEN	No. of donors	Percentage
Negative	4648	80.8%
Positive	1106	19.2%
Total	5754	100.0%

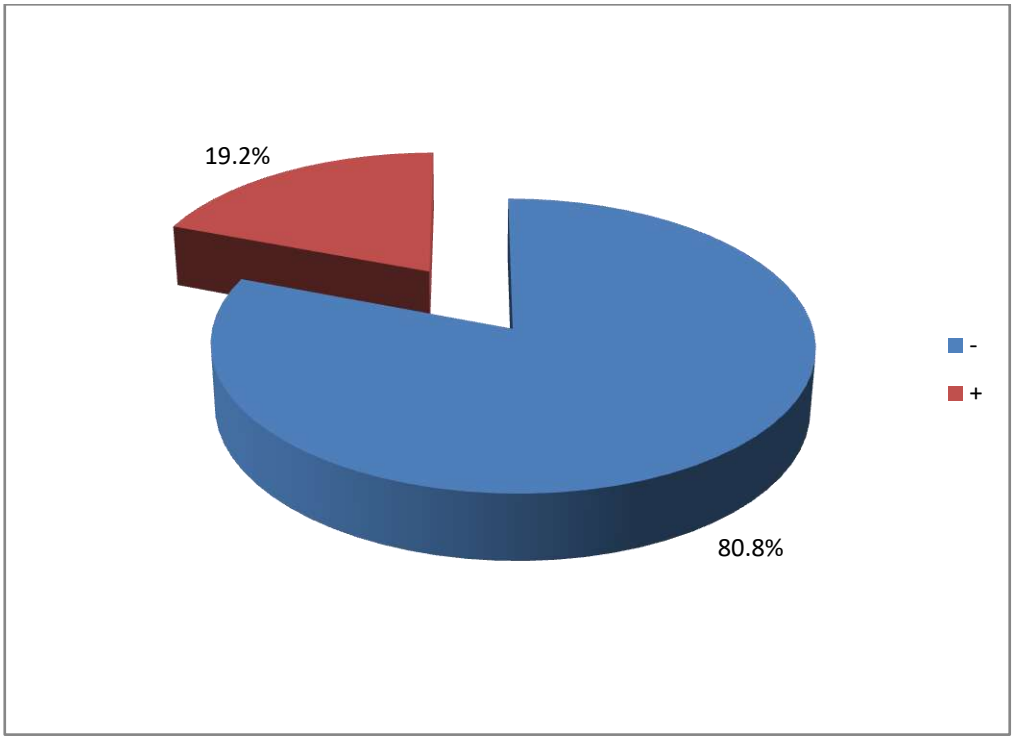

Figure 11 Distribution of E antigen in donors:

Distribution of e antigen in donors

Out of 5754 blood donors, “e” antigen was found in 98.5% (86) of donors and absent in 1.5% (5668).

Table- 12 Distribution of e antigen in donors:

e ANTIGEN	No. Of donors	Percentage
Negative	86	1.5%
Positive	5668	98.5%
Total	5754	100.0%

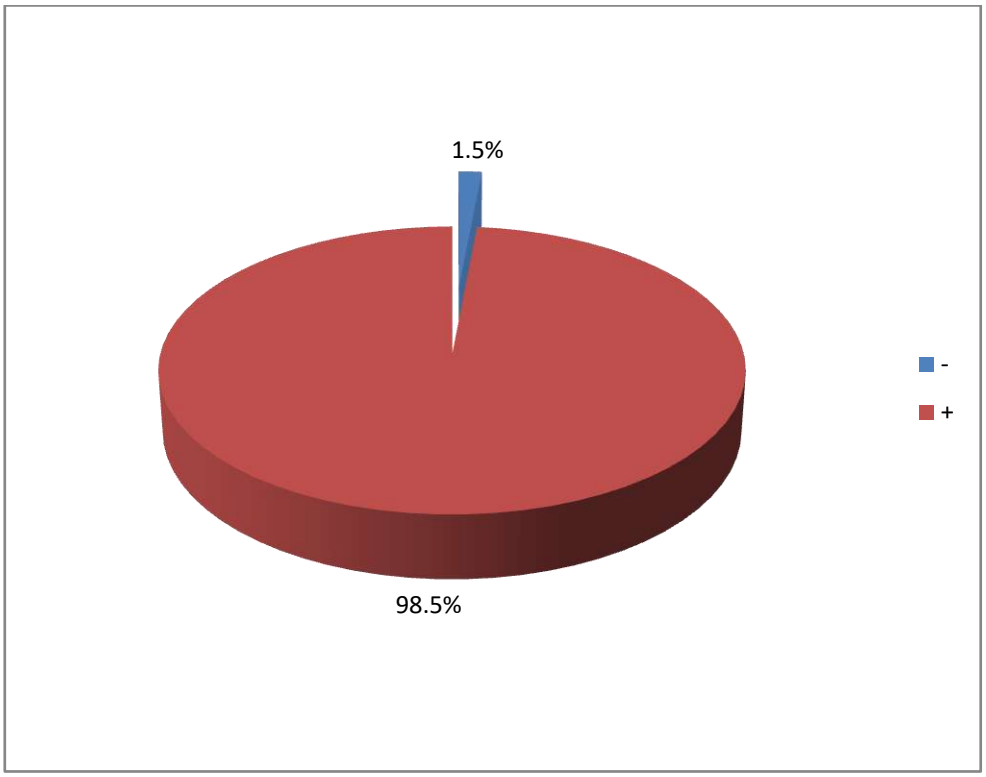

Figure 12 Distribution of e antigen in donors:

Distribution of KELL antigen

Prevalence of Kell antigen in blood donors is present in 3.5% (199) and absent in 96.5% (5555) among 5754 total number of donors.

Table- 13 Distribution of KELL (K) antigen in donors:

KELL ANTIGEN	No. of donors	Percentage
Negative	5555	96.5%
Positive	199	3.5%
Total	5754	100.0%

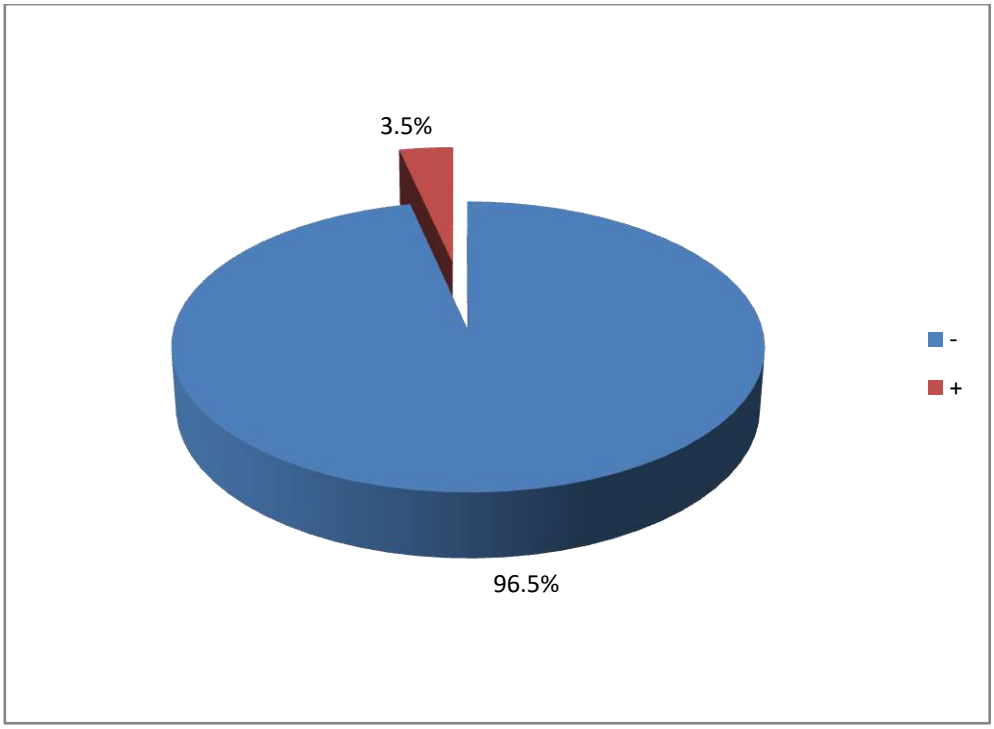

Figure 13 - Distribution of KELL (K) antigen in donors:

DISCUSSION

Antigen frequency identification is an important part of Blood grouping in the transfusion practices and blood banking. ISBT, has recognized 43 blood groups out of these 9 (ABO, Rhesus, Kidd, Kell, MNS, Duffy, P, Lutheran, and Lewis) were reported significant as improper transfusion can cause HDFN and Haemolytic Transfusion Reactions.

The prevalence and antigenicity of various antigens determine the frequency of occurence of that corresponding antibodies. Antibodies against high-frequency antigens are uncommon, whereas alloantibodies against antigens of low/intermediate frequency with high antigenicity are frequent. Blood banking and transfusion specialists are mostly related to reactions between antigens, which are present on red blood cells, and antibodies, which are present in plasma.

Thus, for a transfusion to be safe, blood grouping, cross matching, antibody screening, antibody detection, and red cell phenotyping are crucial. The price of blood banking has gone up as a result of these procedures. The phenotyping of Rh and Kell can be very important in preventing alloimmunization and avoiding negative outcomes in subsequent transfusions in multitransfusion cases, especially in light of the high cost of phenotyping of all clinically critical antigens. The two most significant agents responsible for alloimmunization are Rh and Kell[57]

RH SYSTEM:

Rh blood group system shows extensive polymorphism and allelic frequencies vary with different populations[58] The Rh and Kell antigen frequencies of the study population were compared within the country and abroad. The prevalence of D antigen variation has been seen from 60% to 80% in Southern Franceto 60%–99% in Japan, Burma, and Malaysia[59] The frequency of D-negative person among the Taiwanese population is 0.3%. Hence, no D typing is done in the patients of Taiwan[60] In a study of Akre[61] they found that 62.8% of patients

suffering from sickle cell disease and who were transfused were immunized against Rh and Kell antigens systems. Rh was involved in 44.44% while Kell was involved in 27.78% in sickle cell patients transfused against 38% for both in France[62]

Rh phenotype variation is seen in different populations around the globe. Blood donors and patients are geneticallyhomogenous in a country so it can be said that same Rh phenotypes/genotypes that are observed in blood donors would be present in patients too. It is clinically important to know the common phenotypes/genotypes as it helps in themanagement of patients forming alloantibodies due to transfusions and also the prevention of alloimmunization inmultitransfused patients. Sensitization of fetal red blood cells due to maternal factor results in fatal complications. Haemolytic disease of new born is a challenging part for both clinicians and for transfusion experts as well. Red cell transfusion is a majot risk factor for non “D” Rh immunization. We do not have any non “D” Rh antigen immunoprophylaxis therefore prevention at primary level is important by giving phenotypically matched blood to all the pregnant women. Treatment of haemolytic disease of new born or erythroblastosis fetalis is exchange transfusion but this can be avoided by vaccinating the mother with Rh immunoglobin after the delivery of her first born baby due to Rh incompatibility. The Rh vaccination will destroy any fetal blood cell before mothor’s immune system can develop for its function againt the fetal cells. Considering along with this first and safest treatment further is relevant when treatment modalities like exchange transfusion are also considered in treating haemolytic disease of new born. so, the direct coomb’s test is applied which leads to the diagnosis of Hemolytic disease of new born which looks for maternal anti-D that have already been attached to the red cells. Along with D being the culprit for haemolytic disease of new born furthermore anti c, anti E and anti Kell are also considered as main culprits as well. Majority of these antibodies against Rh antigen are IgG type carrying significant haemolytic transfusion reaction and haemolytic disease of new born.

While we have only few examples of Rh alloantibody that are naturally occurring and are of IgM type ut these are present in minority only. The D antigen holds 50% of all cases in maternal alloimmunization and rest by other minor antigens as well. For these reasons D typing is performed on daily basis on every blood donor and transfusion recipient as well so as to minimise the risks and complications related to it. Anti D, anti C, anti e and anti E all are involved in delayed type of transfusion reaction.

The distribution varied from one population to another considering Age, Sex, ABO groups and among Rh positive and negative individuals. The frequency of Rh positive in our study was 91.9%, whereas only 8.1% were Rh negative. In Cote d'Ivoire, the blood transfusions are done only regarding ABO and RhD antigens exposing patients to high alloimmunization. Various studies conducted to find out the prevalence of D antigen is shown in table below.[63] Various studies conducted showed almost similar to our study.[47,49,64-65] InRoy M, Gupta RK et al, Verma S, Verma A et al[66-67] the incidence of D positive is more common than D negative which varies from 93.7% to 97.8.

Table 14 - Studies showing prevalence of Rh positive and negative antigen

Studies	Rh Positive	Rh Negative
Our study	91.9%	8.1%
Cote d'ivore et al[68]	92.93%	7.7%
Radia A et al[49]	92.29%	7.71%
Das PK et al[64]	94.53%	5.47%
Kumar H et al[65]	93.7%	6.3%

The Antigen frequency of other Rh antigens (C, c, E, and e) of our study was seen, the most prevalent antigen in our study is "e" with 98.5%and the least common antigen was E (19.2%). "e" antigen is most commonly seen in all regions globally.[25,69] Therefore, it is very difficult to find "e" antigen-negative donor for a patient with

alloimmunization against this antigen. Similarly, in most of the other studies “e” is highly prevalent antigen, being present in >90% of the population[70-71] Our results for “e” antigen positive is 98.5% and negative for 1.5% and these are in accordance with other studies from North India which have reported high prevalence of “e” antigen.[72-77]

The frequency of c antigen positive in our study is found to be 60.7% and 39.3% of donors are negative for c antigen**.** Our study results are nearly similar to other studies from the Indian subcontinent.[72-77]However, frequency of positive C antigen seen in our study is 83.8% and absent in 16.2% of donors which is in accordance with similar studies from India.[72-77]The prevalence of “C” antigen is reported as high as 93% in the population of Asian descent[63] and as low as 2.78% from Nigeria. C is the second-most antigen found in India, China, and in Asia'[69] whereas in other population, c antigen is the second most common.[25]

E antigen is the least common antigen found in all regions worldwide. It is a low-frequency antigen but is highly immunogenic and anti-E has been reported as one of the most frequent antibodies in multitransfused patients in India.[78-80] The prevalence of “E” antigen in our study is accounting for 19.2%. Results are seen similar to all other studies from the India.[68,72-77]

Table 15 - Studies showing prevalence of major Rh antigen

STUDIES	**e ANTIGEN**	**E ANTIGEN**	**C ANTIGEN**	**c ANTIGEN**
Our study	98.5%	19.2%	83.8%	60.7%
Nagervadze M at al[70]	100%	23.0%	89.0%	61.0%
Taha JY. Et al[71]	71%	21.0%	73.0%	71.0%
Thakral B et al[72]	98.3%	17.9%	84.7%	60.7%
Makroo RN et al[73]	98%	20.0%	87.0%	58.0%
Shah A et al[74]	100%	16.5%	91.0%	50.5%

Nag I et al[75]	98%	17.4%	88.4%	47.9%
Gundrajukuppam DK et al[76]	98.4%	18.8%	88.0%	54.9%
Gajjar M, Patel T et al[77]	99.07%	17.88%	88.77%	55.89%

KELL SYSTEM:

Among non “D” antigens, “K” is known to be the most immunogenic, followed by c and E.[63] In our study, Kell antigen was found in 3.5% of blood donors enrolled in study which is comparable with frequency in whites. It can be inferred from this that 96.5% of donors are "K" negative. As a result, for "K," 3.5% of recipients of "K" negative blood will receive "K" positive blood. The percentage prevalence of Kell antigen varies from studies to studies conducted from 1.60 to 6.0%[81-82] However, rates reported from North India are as 5.56% and 3.5%[72-73] Our study was similar to the other studies conducted in India[47,51,64,72]In Contrary to France where 9% of individuals are K+ [62] and to Germany where 4% express the K antigen.[83]

Table 16 - Studies showing KELL antigen prevalence

STUDIES	**KELL ANTIGEN**
Our study	3.5%
Garg and Singh *et a*[81]	1.6%
Kahar and Patel et al[82]	1.6%
Thakral *et al*[72]	5.6%
Makroo RN, Bhatia A et al[73]	3.5%
Shah A, Jariwala K et al[74]	1.0%
Gajjar M, Patel T et al[77]	1.78%
Cote d’ivoire et al(68)	0.92%

Demographic details:

AGE:

A total of 5754 blood donors were included in our study. The age range taken into account was 18 to 60. In the study by Garg N. et al, the age range was 18 years to 55 years, whereas in the studies by Behra et al, the age range was 18 to 25 years, and by Chitra et al, the age range was 18 to 52 years.

GENDER:

In a developing nation like India, where donations from women are reported to be lower than those from men due to a variety of sociocultural factors, including cultural customs, social taboos, fear of donating, and a lack of motivation. In our study, there were 1.2% female donors as opposed to 98% male donors.

Table 17 - Studies showing percentage of males and females

STUDIES	MALE	FEMALE
Our study	98.8%	1.2%
Gundarajukuppamet al[76]	97.6%	2.4%
Mangwana et al[84]	97.6%	2.74%
Lamba et al[85]	94.7%	2.4%
Garg P et al[86]	0.23%	99.7%

Rh and Kell antigenic prevalence according to gender:

91.9% of female donors had Rh D positive antigen, compared to 95.7% of male donors. Maximum prevalence of e antigens, 98.6% and 97.1% respectively, were found in both males and women. The minimal prevalence of E antigen was 19.2% in male donors and 18.8% in female donors, respectively. According to gender, no comparison was found in Kell antigen. The following table displays the distribution of Rh

antigens by gender in our and Gundaraj et al. In our study, the prevalence of Kell was 3.4% in males and 4.3% in females.

Table 18 - Studies showing percentage Rh and Kell antigen distribution among males and females

	Gender	**D**	**C**	**C**	**E**	**E**	**KELL**
Our study	M	91.9 %	83.8%	60.7%	19.2 %	97.1 %	3.4 %
	F	95.7 %	81.2%	68.1%	18.8 %	98.6 %	4.3 %
Gundarajkuppamet et [76]	M	94.2 %	88.11 %	54.5%	18.6 %	98.3 %	-
	F	87.5 %	83.33 %	70.45 %	25%	100 %	-

Rh and Kell antigen prevalence in Rh Positive and Rh Negative donors:

Among 5754 donors Rh positive were 5290 and 464 were Rh negative donors. Following table shows comparison between studies.

Table 19 - Studies showing prevalence of Rh antigens in positive and negative donors:

	RH	**C**	**C**	**E**	**E**	**Kell**
Our study	POSITIVE	90%	57.55	20%	98.4%	3.3%
	NEGATIVE	13.1%	97.6%	4.1%	99.1%	5.0%
Sangeeta Pahuja et al[52]	POSTIVE	93.3%	56.04%	17.92%	95.4%	1.84%
	NEGATIVE	5.0%	98.0%	1.2%	100%	1.21%

Rh and Kell antigenic prevalence according to ABO grouping:

Table 20 - Studies showing prevalence of Rh and Kell antigen in ABO blood groups:

	Blood group	**D**	**C**	**C**	**E**	**e**	**KELL**
Our study	A	93.3%	83.5%	62.7%	22.6%	99%	3.4%
	B	92%	84.4%	58.8%	17.7%	98.5%	3.5%
	AB	94.3%	85.8%	56.5%	17.2%	98.4%	4.35
	O	90.4%	82.7%	62.9%	19.5%	98.3%	3.2%
Nippun Prinja et al[55]	A	91.9%	81.9%	66.6%	18.9%	99.5%	2.36%
	B	94.9%	85.5%	57.9%	18.6%	98.99%	2.92%
	AB	93.6%	89.3%	50.6%	19.6%	100%	5.22%
	O	93.6%	86.7%	60.6%	16.2%	99.4%	1.86%

In our study of 5754 donors, the most prevalent blood group seen is B followed by O>A>AB. Among these, antigen distribution was seen different in different blood groups. Following table shows prevalence of Rh and Kell in different blood groups.

This population's antigen frequency aids in the prediction of common alloantibodies in transfused patients. It facilitates the selection of antigen-negative blood for alloantibody patients. For both clinicians and transfusion medicine experts, maternal sensitization to foetal red cell antigens that results in, occasionally deadly, HDN is a difficult problem to solve. Prior red cell transfusions have been demonstrated in previous studies to be the primary risk factor for non-"D" Rh immunisation. Given that there is no immunoprophylaxis for these non-D Rh antigens, significant morbidities can be avoided by donating

phenotypically matched blood to all women under the age of 45. After "D," anti-c, anti-e, and anti-K once more hold the dubious distinction of being frequent HDN offenders. Therefore, the majority of alloimmunizations can be avoided by giving matched blood to all girls under the age of 45. Taking into account the study's demographic findings, which demonstrated that the age and gender of the blood donor had no effect on the distribution of the Rh and Kell antigens, there is no association between the two. On the other hand, an association and relevance are observed with the ABO grouping when Kell and Rh antigens are present.

SUMMARY AND CONCLUSION

To conclude, Knowledge of antigen frequency of RH and KELL antigens would be helpful in serological investigations and transfusion support to multitransfused patients with presence of alloantibodies. This antigen profile of a population may be helpful in devising more cost effective ways of providing maximum benefits with least resources. However, extensive studies need to be done in this field so that treatment decisions can be taken in a more scientific, population specific, and a more cost-effective way. Red cell antigen phenotype frequencies in a population with different groups can help in creating donor data bank and database for the distribution of blood groups for preparing inhouse cell panels and providing proper antigen compatible blood for patients with multiple alloantibodies and also reduce the risk of RBC antigen alloimmunization along with their complications.

Varying frequency and phenotypic expression of major clinically relevant antigens and deriving estimates for underlying ABO and KEL alleles and RH haplotypes in these blood groups systems would help in more rational approach for blood transfusion with appropriate antigen matched blood decreasing alloimmunization and enhancing blood safety. Outcome of such studies can be used to formulate a rare blood group registry at regional and National level and directing patients with antibodies against high frequency antigens, requiring multiple transfusions.

A variety of range of Rh and Kell antigen profile are found in different region, populations and religion. In our study, we found that the most frequent antigen amongst five major antigen of Rh system was “e” (98.5%) whereas “E” (19.2%) was the least prevalent antigen. The order of overall prevalence of Rh antigens was e > C > c > E. In Rh-positive donors (91.9%), the order was e > C > c > E, where in Rh negative (8.1%) were seen. The Kell antigen was found in 3.5% of

donors. We had also found that out of the ABO blood group, B (38.6%) was the most prevalent group whereas AB (8.5%) was the least; most of the donors were Rh positive except few who were Rh negative. The sequence of blood group prevalence among ABO donors was B > O > A > AB. This study can be a tool to build up a database of the donors having their specific Rh antigens. To prevent HDFN, the antenatal Rh phenotyping should done for all pregnant women. In case of patient suffers from adverse transfusion reaction, for all the next times he/she should be transfused with Rh phenotype matched blood. The Rh based data can be used in providing certain antigen negative blood to the patients who are multitransfused and having some sort of alloimmunisation. Hence, this study helps in providing matched blood to recipients to minimize alloimmunization rate and thereby improving blood safety. All the multiple transfused patients, patients depending on transfusions like leukemia patients, hemoglobinopathy patient or aplastic anemia patients along with pregnant mothers should always be transfused with Rh phenotypically matched blood. This study will be helpful in formulating policies regarding pre-transfusion testing and henceforth decreasing the medico legal complications.

No. BFUHS/2K21p-TH/ 150

Date 05/11/22

The Principal,
DMC, Ludhiana.

Subject: **Approval of Plan of Thesis.**

This is to inform you that the Faculty of Medical Sciences in its meeting held on 29.10.2021 has approved the plan of thesis of **Maryada**, a student of your college for **MD Immuno Haematology & Blood Transfusion** along with the names of Supervisor/Co-Supervisor as under:-

Topic Plan of Thesis
To study the distribution of rh and kell blood groups in blood donors.

Supervisor
Dr. Rajesh Kumar
Prof.,
Dept. of I.H.B.T.,
DMCH, Ludhiana.

Co-Supervisor

Dr. Amarjit Kaur
Prof. & Head,
Dept. of I.H.B.T.,
DMCH, Ludhiana.

Dr. Sonia Gupta
Assoc. Prof.,
Dept. of I.H.B.T.,
DMCH, Ludhiana.

The student has to submit the four copies of thesis (along with PDF format) , to the Controller of Examinations, BFUHS, Faridkot, at least six months before the commencement of theory examination, if he/she is otherwise eligible to take the examination. He /She must directed to attach a photocopy of this letter with the forwarding letter while submitting thesis to the University along with the letter of approval of University for change of supervisor/Co-Supervisor, change of topic,(if any).

Dr. S P Singh MS(Oph)
Controller of Examinations

Note :

65. *If any discrepancy found regarding topic of thesis or Supervisor/Co-Supervisor, inform undersigned within one month after issue of this letter.*
66. *The student may submit the thesis as per the schedule already conveyed i.e for May/June examination 30th Nov of the preceding the year of examination and for Nov/Dec examinations 31st May of the year of examination.*

TO STUDY THE DISTRIBUTION OF RH AND KELL BLOOD GROUPS IN BLOOD DONORS

THESIS PROPOSAL

FOR APPROVAL OF SUBJECT OF THESIS TO BE SUBMITTED

IN PARTIAL FULFILMENT OF THE REQUIREMENTS

FOR THE DEGREE OF

DOCTOR OF MEDICINE

In

IMMUNOHEMATOLOGY AND BLOOD TRANSFUSION

OF THE

BABA FARID UNIVERSITY OF HEALTH SCIENCES

FARIDKOT

MARCH 2021

Dr. Maryada

DEPARTMENT OF IMMUNOHEMATOLOGY AND BLOOD TRANSFUSION
DAYANAND MEDICAL COLLEGE & HOSPITAL, LUDHIANA
LUDHIANA, PUNJAB-141001

ABSTRACT OF PLAN OF THESIS

Title	TO STUDY THE DISTRIBUTION OF RH AND KELL BLOOD GROUPS IN BLOOD DONORS
For the degree of	M.D.
Name of the candidate	Dr. Maryada
Supervisor	Dr. Rajesh Kumar, Professor, Department of I.H.B.T, DMCH, Ludhiana
Co-supervisor	Dr. Amarjit Kaur, Professor & Head, Department of I.H.B.T, DMCH, Ludhiana Dr. Sonia Gupta, Associate Professor, Department of I.H.B.T, DMCH, Ludhiana
Institution	Dayanand Medical College and Hospital, Ludhiana
University	Baba Farid University of Health Sciences, Faridkot

Introduction: The blood transfusion aims to ensure adequate and safe blood. The Rh and Kell blood groups are highly immunogenic blood group systems. The antibodies against these antigens can result in severe hemolytic reaction. The transfusion of ABO compatibility but phenotype blood may result in alloimmunization especially in patients who require multiple transfusions in hematological disorders and malignancies. The knowledge about the frequency of the red cell alloimunization is important for minimizing the risk of alloimmunization. It will be beneficial for reducing the transfusion reactions and hemolytic disease of fetus and newborn. This study will aim at providing data regarding the frequency of Rh and Kell antigen with their phenotype expression in blood donors.

Aim of Study: The aim is to study the frequency of Rh and Kell blood group antigens and phenotype among blood donors to compare with different ethnic groups.

Materials& methods: This will be a study of entire one year. It will include voluntary donations and the samples taken will be processed for Rh and Kell antigen typing on Neo iris Immucor automated platform that uses micro-plate haemagglutination technique and commercial antisera for phenotyping.

Clinical Significance: The presence of anti kell and anti Rh antibodies in an indivisual in whom multiple transfusion is done can lead to the extensive transfusion reaction. Such as in Rh negative pregnancies, thalassemia patient where multiple transfusions are required, the knowledge about the phenotyping the donor can prevent the reactions due the alloimmunisation and relatively safe bood can be transfused to the patients.

Keywords: Alloimmunisation, alloantibodies, transfusion reaction, hemolytic disease of new born.

CERTIFICATE OF FACILITIES AVAILABLE

This is to certify that the facilities for work on the subject of thesis titled **"TO STUDY THE DISTRIBUTION OF RH AND KELL BLOOD GROUP IN BLOOD DONORS"** exist in the Department of Immunohematology and Blood Transfusion at Dayanand Medical College and Hospital, Ludhiana and will be provided to the candidate. We will see that the data being included in the thesis are genuine and is collected by the candidate herself under our supervision and guidance.

Supervisor

Dr. Rajesh Kumar

PROFORMA FOR REGISTRATION OF SUBJECT FOR DISSERTATION

1	NAME OF THE CANDIDATE AND ADDRESS	Dr. MARYADA Faqir Chand Rooprai Memorial Nursing Home, Patiala-147001
2	NAME OF THE INSTITUTE	DAYANAND MEDICAL COLLEGE AND HOSPITAL
3	COURSE OF STUDY AND SUBJECT	MD IMMUNO HEMATOLOGY AND BLOOD TRANSFUSION
4	DATE OF ADMISSION OF COURSE	27 JULY 2020
5	TITLE OF THE TOPIC	TO STUDY THE DISTRIBUTION OF RH AND KELL BLOOD GROUPS IN BLOOD DONORS.

6. BRIEF RESUME OF THE INTENDED WORK

6.1 NEED FOR THE STUDY

Blood transfusion can carry immediate or delayed immunological reactions. The most serious is hematological transfusion reaction by antibody incompatibility. Knowledge about the frequency of red cell antigen phenotype is very important for creation of donor bank data and to minimize the risk of alloimmunisation. The Rh and Kell are highly complex blood group systems, and alloimmunisation to these blood groups can complicate the transfusion. Therefore the knowledge of these blood groups in a given population is relevant for the better planning and management of the blood transfusion. It is always helpful in managing the cases of multiple transfusion like thalassemia, sickle cell anemia, cancer patients and patient on dialysis. In such multi transfused patients it is recommended that Rh and kell matched blood should be transfused. It may also reduce the reported RBC antigens alloimmunization along with their possible complication such as hemolytic transfusion reaction and hemolytic disease fetus and newborn. By knowing about the phenotype frequencies in a population, it can help in providing proper antigen compatible blood for the patient with multiple alloantibodies and reducing the risk of RBC antigen alloimmunization along with their complications. Antigen of the major blood group systems plays very important role in determining the outcomes of transfusion in recipient of the blood and blood components. In those cases, where clinically significant antibodies are identified in patient's serum, antigen negative donor unit can easily be retrieved from the donor data based available blood groups in department.

Among the immunogenic antigens of blood group, the Kell antigen system is ranked second behind the RH antigen. The infrequent cases of HDN caused by Kell immunization tend to result in severe fetal anemia because maternal anti-Kell target fetal red blood cell (RBC) precursors, suppressing the fetal production of RBCs. This requires determination of immunological characteristics of blood components and blood recipient by performing immune hematology analysis such

as phenotyping.[1] The prevalence of red cell antigen and phenotype frequencies differs in different populations. If we know about the prevalence of blood group antigens, we can prevent alloantibodies formation in multiple transfused patients against minor antigens. The finding in our studies will introduce a plan of better care for the patient. Apart from their relevance in blood transfusion practice and pregnancy management, blood group antigens can inexpensively be applied to medico-legal issues, such as disputed parentage.

The alloantibodies which frequently develop and are encountered during compatibility testing are primarily against antigen related to Rh and Kell blood groups system , antibodies against these antigens are implicated in case of hemolytic transfusion reaction and hemolytic disease of new born and fetus are regarded as clinically significant if these react in indirect antiglobulin test at 37' c. [2,3]

Thus, it is important to know the frequencies of the various antigens when dealing with patients who have developed multiple antibodies. This information is necessary to predict the availability of blood unit that lack the corresponding antigen. This intervention will not only reduce the rate of alloimmunization in the patients but will also save the time and recourses.

6.2 REVIEW OF LITERATURE

The ultimate goal of Blood Transfusion services is to ensure safe and adequate blood supply to the patient to minimize the development of transfusion reactions. In red blood cell transfusion, transfused RBC's should have an acceptable survival rate, and there should be no significant destruction of the recipient's own RBCs.

Blood groups systems can be defined as the set of allotypic variations genetically transmitted, detected by antibodies on the surface of on the red blood cell membrane. The development of the antiglobulin test for the detection of non-agglutinating antibody lead to the discovery a lot of blood group antigens. In multi transfused patients and antenatal patients it is recommended that Rh and Kell matched blood should be transfused. This is possible only if know the frequencies of the antigens in the donor population. The study of these systems for the blood transfusion needs, demonstrates the existence of genetic variation among human populations.

Currently, there are thirty-three major blood group systems[4], but analyses recommended in the usual situation are ABO, Rh, and Kell typing and detecting red cell antibodies. The blood grouping is extended to major alloantigens of Rh (D, C, E, c, e) and Kell (K) systems where allogenic differences persists and multi transfused patients are not spared of alloimmunization.

The Rh blood grouping system was discovered in 1940 by Karl Landstinier and A.S weiner. RHD and RHCE are two closely linked genes located on chromosome 1 that control expression of Rh proteins.[5] Since then a number of distinct Rh antigens have been identified but the first and the most common one called Rh D, causes the most severe immune reaction and is the primary determinant of the Rh trait. The Rh antigen resides on the transmembrane protiens are an integral part of the RBC membrane.[6] The five common Rh antigen are D, E, C, c and e with their specific antibodies. Another important Rh antigen expression is RHAG (Rh- associated Glycoprotien) and resides on chromosome 6.[7] Rhesus (Rh) blood group is one of the most

complex and polymorphic blood group systems. Observation by Levine *et al*. that the development of stillborn fetus (hemolytic disease of the newborn [HDN]) was associated with immune reaction to paternal antigens led insights into the complexities of Rh blood group system.[8] The Rh antigen are highly immunogenic and most of the Rh antibodies should be considered as a potential cause of hemolytic transfusion reaction and heamolytic disease of newborn and fetus.. Years after research, Rh- immune globin, a purified preparation of id IgG anti-D, is given to the D-negative woman during pregnancy and following delivery of a D- Positive fetus.[9]

The Kell blood group system was discovered in 1946. It was named for Mrs. Kelleher, a patient in whom anti-Kell antibodies had resulted in hemolytic disease of her newborn child. The gene KEL, located on chromosome 7 at position 7q33, is organize into 19 exons of coding sequence.[10] The Kell Blood system consists of 36 high- prevalence and low-prevalence antigen, but the original K antigen remains of prime importance in transfusion medicine and Haemolytic disease of new born. The 36 antigens included in the kell blood group system, designated by the symbol KEL or 006 by the ISBT. Kell blood group antigens are found only on RBC's. Total number of K antigens sites per RBC is quite low; only 3,500 up to 18,000 sites per RBC.[11] Despite its lower quantity, K is very immunogenic. The most anti-K appears to be induced by pregnancy and transfusion.[12] Anti-K is the most common antibody seen which is usually IgG types and naturally occurring IgM antibodies are rare. Anti-Kell is the most common immune red cell antibody outside ABO and Rh systems and is considered clinically significant, both from point of view of causing severe hemolytic disease of the fetus and newborn and hemolytic transfusion reaction.[13] The fetal anemia with anti-K HDFN is associated with suppression of erythropoisis due to destruction of erythroid precursor cells, which can be additional to destruction of the circulating antigen positive RBC's, as seen in anti-D HDFN. The kell glycoprotein is expressed on fetal RBC's at a much earlier stage of erythropoisis than Rh antigen.[14] The Kell blood group system is complex. The Kell locus is highly polymorphic

and gives rise to many Kell antigens. The k antigen is more common than the K antigen in most populations, the K-k+ phenotype is found in 98% of Blacks and 91% of Caucasians.[15]

Prevalence of Rh and Kell antigens in a population varies with race, ethnicity, and geographical location. Phenotypic distribution and allelic frequencies of blood group antigens are one of the major determinants of alloimmunization risks. Phenotypic profiling and assessment of allele frequencies help in evaluating the distribution of antigens in a particular population and at the same time helps in estimating the chances of getting compatible blood units for patients who have developed multiple antibodies.[16]

Thakral et al. reported for Northern India a K prevalence of 5.68%, which almost resembles the European situation, for instance 7.82% in Germany.[17]

A study of New Delhi, where Samples from randomly selected blood donors (both voluntary and replacement) coming for blood donation were collected for extended antigen typing during January 2009 to January 2010, a total of 3073 donors were typed during the study period. The most common Rh antigen observed in the study population was e (98%) followed by D (93.6%), C (87%), c (58%) and E (20%). The frequency of the Kell antigen (K) was 3.5 per cent, while that of Cellano (k) was 99.97 per cent. (2009).[18]

In Cote d'Ivoire study, samples of 605 blood donors for phenotypic profile of Rh and Kell, were found to be representing 92.93% of the blood donors to be RhD Positive while 46 blood donors representing 7.07 were found to be RhD negative. In the Kell blood group system, 5 blood donors (0.77%) were typed as K antigen positive and 645 (98.08%) as k antigen positive antigens. Accordingly, the K−k+ phenotype was the most common in these donors (98.92%). (2014).[19]

Another study of Phenotype frequencies of Rh and Kell blood groups, shows the result of clear predominance of Rh1 (D) positive (89.81%) compared to Rh-1 (d) negative (10.19%). CcDec was th most common phenotype (38.95%), followed by ccDee, ccdee and CcDEe. For the Kell system, the predominance of Kell-1 subjects was clearly observed

at frequency of 93%. The Rh D allele was the most prevalent (68.08) among Rh blood type alleles while the Kell-1 (96.44%) was frequent among the alleles of kell blood group system.(2016).[20]

In a latest study in 2019 of distribution of RH and Kell (K) blood group antigens among blood donors in a tertiary care hospital, on phenotyping for Rh and Kell antigens ‘e’ antigen have the ubiquitous distribution and was found to have the highest frequency 486 (97.2%) followed by ‘D’ antigen 472 (94.4%), ‘C’ antigen 426 (85.2%), ‘c’ antigen 320 (64.0%) and ‘E’ antigen 103 (20.6%). Overall frequency of Kell (K) antigen was only 2.6%.[21]

Hence, The Knowledge of prevalence of different blood group antigens in any population is very important for department of Immune Hematology and Blood Transfusion and Transfusion services policies. The distribution of Rh and Kell antigen varies from race to race and among different ethnic groups. It is always helpful in managing the cases of multiple transfusions like thalassemia, sickle cell anemia, cancer patients and patients on dialysis etc., who are prone to develop antibodies against blood group antigens. Antigens of the major blood group systems play a very important role in determining the outcomes of transfusion in recipients of blood and blood components.

6.3 AIMS AND OBJECTIVES OF THE STUDY

- To study the pattern of Rh and Kell blood group antigens and phenotypes among blood donors and to compare them with different groups

7. MATERIALS AND METHODS

7.1 SOURCE OF DATA

Sample data will be collected during period of 1 year from 1st March 2021 to 28th Feb 2022, all voluntary blood donors with the written consent of the donor at the time of screening

7.2 METHOD OF COLLECTION OF DATA

Inclusion Criteria:

•The whole blood collected in Integral bags.

Exclusion Criteria:

•The whole blood collected in Single bags, Double bags and Triple bags.

•Donors testing positive for HBsAg, HCV, and HIV antibodies and syphilis

After the blood collection procedure is performed as per the transfusion medicine technical manual guidelines, the tube containing EDTA as an anticoagulant will be selected for antigen typing. The sample taken will be processed on Neo Iris Immucor automated platform that uses microplate heamoagglutination technique for typing with IgM monoclonal commercial antiserum for Rh and Kell (K) phenotyping. Rh phenotyping will be done by using monospecific antisera:

Anti-D, anti-E, anti-C, anti-c, anti-e and kell phenotyping will performed by using anti-K.

Any NTD (no type determined) results determined by the instrument well be further tested and confirmed using the test tube method.

OUTCOME

The knowledge of antigen phenotype frequencies in a population with different groups can help in creating donor data bank and database for the distribution of the of blood groups and preparing inhouse cell panels and providing proper antigen compatible blood and reducing the risk of alloimmunization.

STATISTICAL ANALYSIS

Data will be described in terms of range; mean ±standard deviation (± SD), median, frequencies (number of cases) and relative frequencies

(percentages) as appropriate. All statistical calculations will be done using (Statistical Package for the Social Science) SPSS 21version (SPSS Inc., Chicago, IL, USA) statistical program for Microsoft Windows

7.3 DOES THE STUDY REQUIRE ANY INVESTIGATIONS OR INTERVENTIONS TO BE CONDUCTED ON PATIENTS OR OTHER HUMANS OR ANIMALS? IF SO, PLEASE DESCRIBE BRIEFLY.

No.

7.4 HAS ETHICAL CLEARENCE BEEN OBTAINED FROM YOUR INSTITUTION IN CASE OF 7.3?

Attached here with.
